CATAPULTING AND ARRESTING GEAR FORCING FUNCTIONS
FOR AIRCRAFT STRUCTURAL DESIGN

MIL-STD-2066(AS)

1. This military standard is approved for use by the Department of the Navy, and is available for use by all Departments and Agencies of the Department of Defense.
2. Beneficial comments (recommendations, additions, deletions) and any pertinent data which may be of use in improving this document should be addressed to: Commanding Officer, Naval Air Engineering Center, Engineering Specifications and Standards (ESSD), Code 93, Lakehurst, N.J. 08733, by using the self-addressed Standardization Document Improvement Proposal (DD Form 1426) appearing at the end of this document, or by letter.

MIL-STD-2066(AS)

FOREWORD

This document summarizes loads, accelerations, velocities, and other parameters statistically analyzed and extracted from test data representative of the various shipboard and shore based launching and recovery equipment employed by the U.S. Navy. In determining the volume of information to be presented, every effort has been made to condense the data and yet present it, as much as possible, in a form that requires the least amount of additional calculations by the user. The data shown herein may be used to derive time histories of loads and accelerations for the design conditions of MIL-A-8863 "Airplane Strength and Rigidity, Ground Loads for Navy Procured Airplanes" and MIL-A-8866 "Airplane Strength and Rigidity, Reliability Requirements, Repeated Loads, and Fatigue."

MIL-STD-2066(AS)

1. SCOPE

1.1 General. The information contained herein presents loading characteristics, associated parameters, and methods to be used in calculating the catapulting and arresting loads of MIL-A-8863 and MIL-A-8866 for the design of U.S. Navy airplanes operating from shipboard and shorebased launching and recovery gears. A listing of such gears for which data is contained herein is given in Table 1.

2. REFERENCED DOCUMENTS

2.1 Issues of documents. The following documents of the issue in effect on date of invitation for bids or request for proposal, form a part of this standard to the extent specified herein.

SPECIFICATIONS

MILITARY

MIL-A-8863	Airplane Strength and Rigidity - Ground Loads for Navy Procured Airplanes
MIL-A-8866	Airplane Strength and Rigidity - Reliability Requirements, Repeated Loads, and Fatigue
MIL-A-8868	Airplane Strength and Rigidity - Data and Reports

(Copies of specifications, standards, drawings, and publications required by contractors in connection with specific procurement functions should be obtained from the procuring activity or as directed by the contracting officer.)

2.2 Other publications. A listing of Navy publications which include loading and performance behavior of equipment contained herein is presented, for reference only, in Table 2.

¹ The methodology used in deriving the curves of MIL-STD-2066(AS) reflect structural requirements. NAEC performance charts are based on different methodology; therefore, some differences exist.

² Charts are applicable per dates given; NAEC should be consulted for most recent bulletins.

4. GENERAL REQUIREMENTS

4.1 Description of forcing functions. The forcing functions are presented as load versus stroke data. The form of presentation is adjusted to provide condensed and yet readily usable data. This necessitated presentation of data in basically three different forms. For catapulting, the data are presented in a tabular form, nondimensional for the shorebased catapults and dimensional for the shipboard catapults. For arresting, they are presented in a graphical nondimensional form. The equation for the data that are presented in a nondimensional form is:

$$L = \frac{F R}{C M V^2}$$

where: L = nondimensional load

F = catapult tow force or arresting force parallel to the deck or ground, pounds

C = correction factor; for catapulting C = 1

R = total stroke for catapulting or total runout for arresting, feet

M = airplane mass, slugs

V = catapult end speed (including effects of rolling friction and aerodynamic drag, but not thrust) or engaging speed, feet per second

W = airplane weight, pounds

The nondimensional stroke is defined as $\frac{X}{R}$ where X is the value of stroke or runout in feet.

4.2 Tolerance limits of forcing functions. The catapulting and arresting forcing functions presented herein have been derived from empirical analyses of data obtained from a large number of both deadload and airplane tests. In general, the test results include the effects or perturbations in loading behavior due to wear, temperature, manufacturing tolerances on component parts of the gear, installation tolerances (from ship to ship and from one location to the other on a given ship), etc. These effects are presented in the form of mean values and tolerance limits. Such limits were determined by statistical analyses of the large number of records of time histories of loads, accelerations, velocities, stroke, etc. The upper and lower limits about the mean are stated as 90-90 probability limits. This means that there is 90 percent confidence that 90 percent of the data as obtained in practice will fall within these limits at each stroke position. In the discussion and the examples that follow, the force and the nondimensional load shall have the following notations:

F_u = force at upper 90-90 probability limit or upper boundary, pounds

L_u = nondimensional load at upper 90-90 probability limit or upper boundary

F_M = mean force, pounds

L_M = mean nondimensional load

F_L = force at lower 90-90 probability limit or lower boundary, pounds

L_L = nondimensional load at lower 90-90 probability limit or lower boundary

4.3 Nondimensional load-stroke diagrams - derivation of. The nondimensional load-stroke diagram is a plot presenting the nondimensional load L as ordinate versus the nondimensional stroke X/R as abscissa. Such a presentation permits derivation of numerous dimensioned diagrams from a single diagram. The diagram is derived from a statistical analysis of a substantial number of catapult launch and arrestment records which are first normalized to the same base and then nondimensionalized. Slices are made at frequent intervals of stroke to obtain load variation and thus establish the upper and lower 90-90 probability envelopes. Within the boundaries of these envelopes, a multitude of diagrams can be drawn. These diagrams, however, must satisfy the constant area requirements under the nondimensional load-stroke diagram of paragraph 4.4. For simplicity and standardization, however, a 90-90 probability diagram is formed following the envelope upper boundary during the early portion of the stroke but crossing over and picking up the envelope lower boundary during the later portion of the stroke to satisfy the constant area requirement. The other 90-90 probability diagram is defined as the reverse of this. The mean load lies midway between the two extremes of the envelope boundaries. The maximum load is defined as the highest value of nondimensional load occurring on either diagram or on a connecting line. Connecting lines are used to completely describe the 90-90 probability envelope boundaries. Figure 1 shows the upper 90-90 peak load occurring on a connecting line for this particular case. For other cases it may occur during the early or the later portion of the stroke. Figure 1 also gives typical nomenclature for all nondimensional arresting load-stroke diagrams. The catapult load-stroke diagrams are derived similarly but are presented in a tabular form and are dimensioned for the shipboard catapults. This was done because such a presentation permitted retention of the general applicability without increasing the number of tables required. The nomenclature of the catapult load data is the same as that shown in Figure 1 except for the absence of the oscillatory loads.

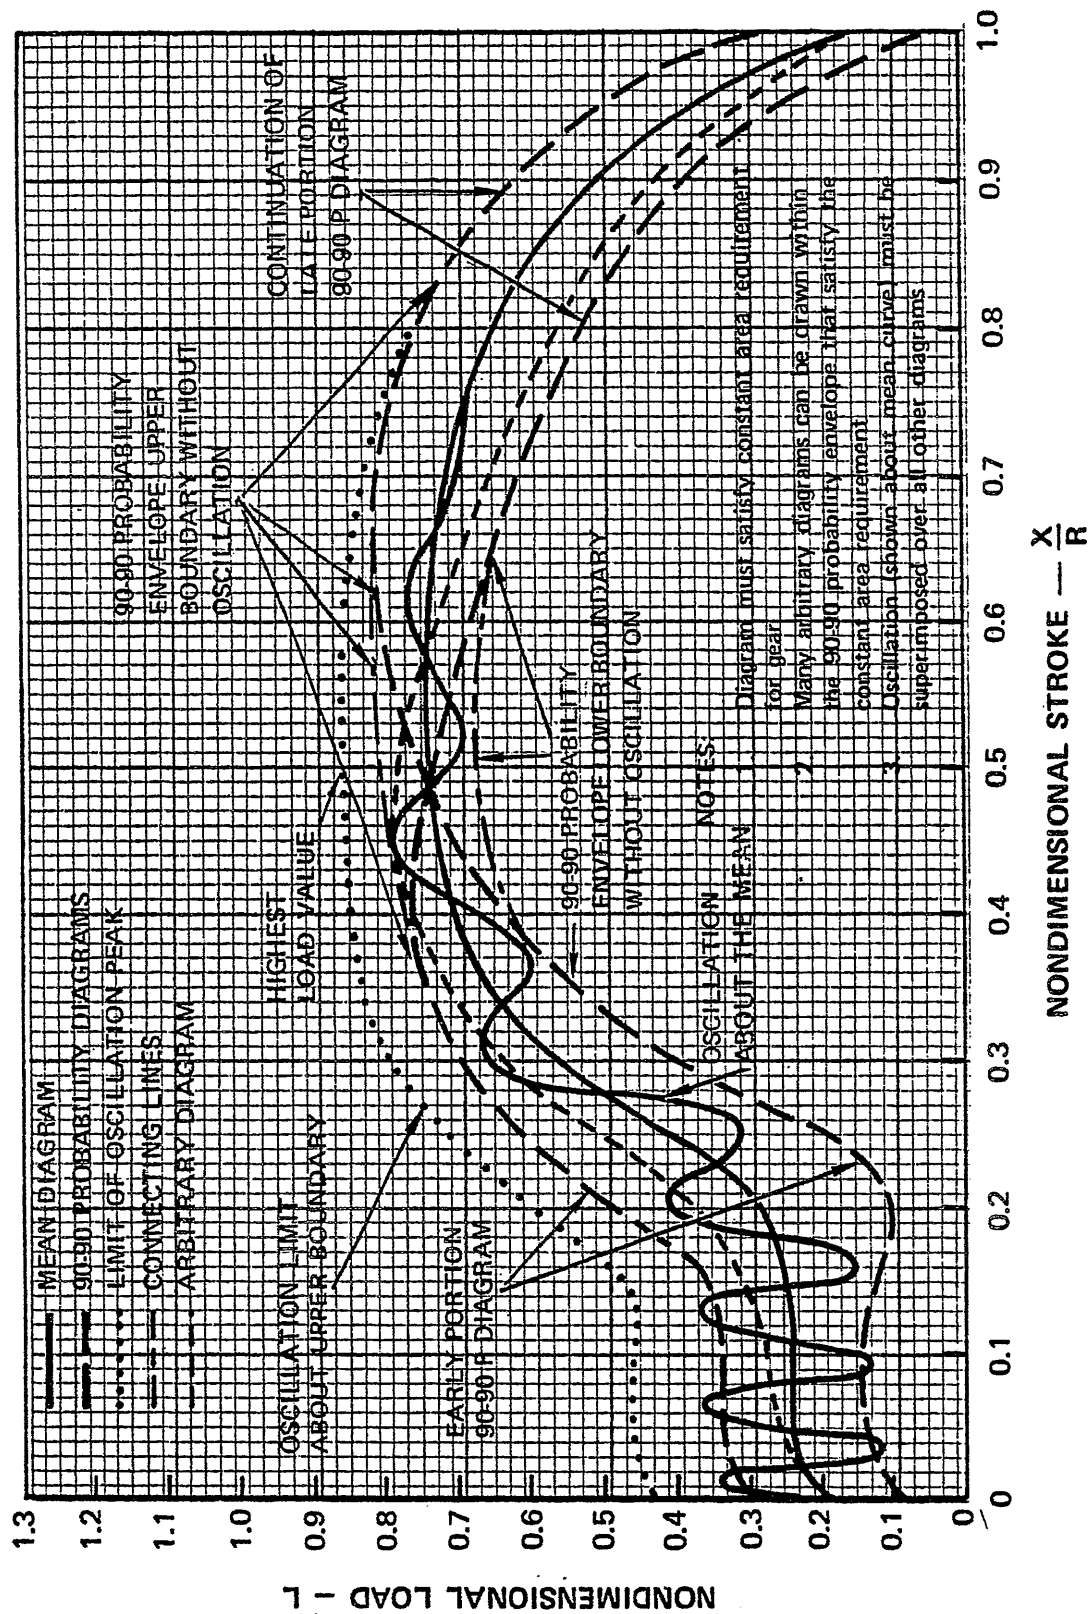

FIGURE 1. Load versus Stroke - Nondimensional Diagram Nomenclature for Arresting

4.4 Area under the nondimensional load-stroke diagrams. To determine the area constraint for catapulting, consider the energy balance equation:

$$\frac{1}{2} MV^2 = \int_0^R [F - F_F - F_D] dX$$

where: F_F = force of friction

F_D = force of aerodynamic drag

or

$$\frac{R}{MV^2} \int_0^1 FdX/R = .5 + \frac{1}{MV^2} \left[\int_0^R F_F dX + \int_0^R F_D dX \right]$$

The left hand term is the area under the nondimensional load-stroke diagram. The second term of the right-hand side of the above equation has been evaluated for different catapults, extreme ranges of endspeeds, and gross weights using the equations of 5.2.6.1.1 for friction and drag, and has been found to be nearly equal to .01. Therefore the area under the nondimensional load for catapulting shown herein and the area that has been used for the derivation of the numerical load-stroke tabulations are based on an area under the nondimensional load-stroke diagram equal to .51.

To determine the area constraint for arresting, the following energy equation applies:

$$\frac{1}{2} MV^2 = \int_0^R [F + F_F + F_D - T] dX$$

where: T = airplane thrust

or

$$\frac{R}{MV^2} \int_0^1 FdX/R = .5 + \frac{1}{MV^2} \left[\int_0^R TdX - \int_0^R F_F dX - \int_0^R F_D dX \right]$$

For the purpose of making the load-stroke diagrams presented herein as general as possible, a constant value of thrust = .4W (base thrust) was used throughout the stroke. A constant value of engaging speed (base engaging speed) for each gear was also used (see Section 5 for corrections required for other values of thrusts and engaging speeds). The sum of the integrals on the right-hand side of the equation above has been evaluated for all gross weights using again for friction and drag the equation of 5.2.6.1.1. This sum has been found to vary very little for each gear. The corresponding areas are .50 for the E-15, .54 for the MK 7-1, .55 for the MK 7-2 and MK 7-3, and .57 for the M-21 gear.

5. DETAIL REQUIREMENTS

5.1 Launching gear (catapult loads).

5.1.1 Types of catapults. The data presented herein apply to the C7, C11-1, C13, and C13-1 shipboard catapults and the CE1-3 shorebased catapults

5.1.2 Catapult tow force load-stroke tables. Data for catapult load-stroke curves are given in a tabular form. Each table has been arranged to show for a specific catapult the upper, mean, and lower boundary value of the horizontal tow force versus stroke; in dimensional form for shipboard catapults and in nondimensional form for the shorebased catapult.

5.1.2.1 Shipboard load-stroke tables. For shipboard catapults numerical load versus numerical stroke data are shown in Tables 3 through 32 for specific airplane weights and catapult energy levels. The peak load attained during a launch is underlined for each weight. Catapult energy level is expressed as accumulator pressure setting for the variable pressure C7, C11, and C13 catapults, and as control selector valve (CSV) setting for the constant pressure C13 catapults.

5.1.2.2 Shorebased load-stroke tables. Due to the variable total stroke R of the shorebased catapult, the load-stroke data is given in Table 33 in nondimensional form to minimize the number of tables required.

5.1.3 Catapult stroke.

5.1.3.1 Shipboard catapult total stroke values. The following values of the total stroke, R, are used for each catapult:

<u>Catapult</u>	<u>Total Stroke, R, feet</u>
C7	247
C11-1	205
C13	243
C13-1	302

5.1.3.2 Shorebased catapult total stroke values. To change the nondimensional load-stroke data of Table 33 to dimensioned load and stroke values, two values of total stroke, R, must be used as follows:

- (a) Airplane total stroke values. The curve of Figure 2 represents the total stroke due to all forces acting during the launch. This curve is used to dimension the nondimensional stroke value.
- (b) Interim total stroke values. The curve of Figure 3 represents the total stroke due to tow force only. It is used to dimension the nondimensional value of the catapult tow force, F, from the nondimensional load, L, given in Table 33.

5.1.4 Catapult energy level. To determine the accumulator pressure or CSV setting for shipboard catapults the minimum catapult end speed, $v_{cat\ rein}$, must be found. This is found by subtracting from the minimum airplane launch

MIL-STD-2066(AS)

speed, V_{min} , the minimum wind over deck WOD_{min} , and the end speed increment due to engine thrust, V_{ET} is determined by airplane performance while WOD_{min} and the criteria for determining V_{min} are defined in the detail specification. Having thus determined $V_{cat min}$, the accumulator pressure is found from Figure 4.1, 5.1, 6.1, 7.1, 8.1, 6.1, 10.1, 11.1, 12.1, and 13.1 as a function of airplane weight and $V_{cat min}$.

5.1.5 Shorebased catapult end speed. To change the nondimensional load data presented in Table 33 to dimensional load values, the value of the end speed must be determined. This is the airplane ground speed at the instant of tow force cutoff.

5.1.6 Peak catapult force. The peak catapult force attained during a shipboard launch as a function of weight and catapult energy level is shown in Figures 4.2, 4.3, 5.2, 5.3, 6.2, 6.3, 7.2, 7.3, 8.2, 8.3, 9.2, 9.3, 10.2, 10.3, 11.2, 11.3, 12.2, 12.3, 13.2 and 13.3. Separate families of curves are given for the upper or maximum and mean values of the peak load. The minimum values of peak load are not shown in this figure but may be obtained from the load-stroke tables. For obtaining the peak loads for intermediate values of airplane weights and catapult energy levels linear interpolation may be used. For shorebased catapults the peak catapult force must be computed.

5.1.7 Catapult primary loading rate. The catapult primary loading rates expressed in g's per second, is imposed on the airplane during the initial stages of the catapult operation. The values of the primary loading rate as a function of weight and accumulator pressure are given in Figures 4.4, 4.5, 5.4, 5.5, 6.4, 6.5, 7.4, 7.5, 8.4, 8.5, 9.4, 9.5, 10.4, 10.5, 11.4, 11.5, 12.4, 12.5, 13.4, 13.5. Separate families of curves are given for the upper or maximum and mean values of the primary loading rate. The lower or minimum value of primary loading rate can readily be obtained since it is the same amount below the mean as the upper is above the mean. For obtaining the primary loading rates for intermediate values of airplane weights and accumulator pressures linear interpolation must be used.

5.1.8 Sample of calculations.

5.1.8.1 Sample of calculations for shipboard catapults.

Given data: Airplane launch weight - 45,000 pounds
 C7 catapult, total stroke, R - 247 feet
 Airplane minimum launch speed, V_{min} - 148 knots
 Minimum wind over deck, WOD_{min} - 15 knots
 End speed increment due to engine thrust, V_{ET} - 6 knots

Data to be

determined: (a) Accumulator pressure

(b) Catapult primary loading rate

(c) Catapult peak tow forces for each of the following conditions:

(1) Upper boundary

MIL-STD-2066(AS)

- (2) Mean
- (3) Lower boundary
- (d) Load-stroke for the upper boundary

Solution: (a) Accumulator pressure -

$$\begin{aligned} V_{cat_{min}} &= V_{min} - WOD_{min} - V_{ET} \\ &= 148 - 15 - 6 \end{aligned}$$

$$V_{cat_{min}} = 127 \text{ knots}$$

From Figure 4.1, for 127 knot end speed and launch weight of 45,000 pounds, an accumulator pressure of 450 psi is obtained.

- (b) Catapult primary loading rate - From Figures 4.4 and 4.5, upper boundary and mean catapult loading rate values are 10.15 and 8.25 g's per second, respectively. The lower boundary value is obtained as $8.25 - (10.15 - 8.25) = 6.35$ g's per second.

- (c) Catapult peak tow forces -

- (1) Upper boundary - Interpolation is required using Table 3, as follows:

F_U for 40,000 lb airplane at 49 ft and at 450 psi = 164.9 kips

F_U for 50,000 lb airplane at 49 ft and at 450 psi = 176.5 kips

delta weight tabulation = 10,000 lbs;
corresponding delta load = 11.6 kips
delta weight this case = 5,000 lb over 40,000 lb

F_U for 45,000 lb airplane =

$$\left(\frac{5,000}{10,000} \times 11.6 \right) + 164.9 = 170.7 \text{ kips or } 170,700 \text{ lbs}$$

The peak tow force can be also obtained by using Figure 4.2.

- (2) Mean - By interpolation using Table 4, or using Figure 4.3 $F_M = 157,600 \text{ lbs}$

- (3) Lower boundary - By interpolation using Table 5, $F_L = 144,500 \text{ lbs}$

MIL-STD-2066(AS)

- (d) Load-stroke data for the upper boundary - In the dynamic analysis requirement of MIL-A-8863 it is necessary to have data for the relationship between the actual catapult stroke, X , and the catapult tow force, F , which acts on the airplane. This is obtained either directly or by straight line interpolation using the tabulated numerical load-stroke diagram. Using Table 3 and interpolation., the upper boundary diagram is formed as shown in Table 34.

TABLE 34. C7 Catapult Tow Force vs Stroke for a 45,000 Pound Airplane

Stroke (feet)	F_U (lbs)	Stroke (feet)	F_U (lbs)
0	54,800	86	160,000
.2	76,150	99	155,050
1.2	123,750	111	150,550
2	135,500	124	145,650
6	157,100	136	139,600
12	163,700	148	133,250
19	166,550	161	128,350
25	167,350	173	123,750
31	168,450	185	119,300
37	169,650	198	114,200
49	170,700	222	105,250
62	167,450	247	96,100
74	164,600		

MIL-STD-2066(AS)

5.1.8.2 Sample of calculations for shorebased catapults.

Given data: Airplane launch weight - 37,685 pounds
 Type catapult - CE1-3
 End speed requirement - 150 knots
 Airplane thrust - 13,200 pounds (.35W)

Data to be determined: Load-stroke for the upper boundary

Solution: Load-stroke - To obtain the relationship between the catapult stroke, X, and the catapult tow force, F, the following operations are performed:

- (a) From Table 33 interpolate between 30,000 and 40,000 lbs, to get the desired nondimensional load values of L for the given airplane weight. These values are shown in the second column of Table 35 at different X/R values.
- (b) From Figure 2, using the given data, solve for the airplane total stroke, R, hence $R = 1,010$ feet.
- (c) The catapult stroke, X, may be found by multiplying the non-dimensional stroke, X/R, value by the R value of 1,010 feet. The values of stroke are shown in the last column of Table 35.
- (d) To calculate the tow force, F, the value of the interim total stroke must be used. This value, obtained from Figure 3, is 1,320 feet.

$$\text{Hence } F_u = \frac{LUMV^2}{R}$$

$$F_u = \frac{LU \frac{37,685}{32.2} \times (150 \times 1.689)^2}{1,320}$$

$$\text{or } F_u = 56,908.9 \times L$$

and F is determined by substituting the values of L, shown in Table 35, as a function of X/R.

- (e) Tabulation of the tow force for the upper boundary is shown in the third column of Table 35.

MIL-STD-2066(AS)

TABLE 35. Calculation of the CE1-3 Catapult Tow Force vs Stroke for a 37,685 Pound Airplane

Nondimensional Values From Table 33		Dimensional	
$\frac{X}{R}$	L_U	F_U (lbs)	X (feet)
(1)	(2)	(3)	(4)

MIL-STD-2066(AS)

5.2 Recovery gear (arresting loads).

5.2.1 Arresting gears. The data herein are presented for two types of arrestments, i.e., routine and emergency. The gears used for routine or normal arrestments are the shipboard arresting gears, MK7-1, MK7-2, and MK7-3 and the shorebased M-21 gear. There are many emergency arresting gears in use but data for only the E-15 gear are shown.

5.2.2 Nondimensional load-stroke diagrams. Diagrams of nondimensional load versus nondimensional stroke are presented for specific airplane gross weights in the figures shown in Table 36. Each figure shows, for each gross weight, three smooth curves and an oscillatory curve. The three curves are the upper, the lower 90-90 probability diagrams, and the mean. The oscillatory curve will be discussed in paragraph 5.2.3. For weights not shown in Table 36 interpolation must be used to obtain the nondimensional load.

TABLE 36. List of Figures Showing Nondimensional Load vs Stroke Curves for Specific Airplane Weights and Arresting Gears

Aircraft Weight (lbs)	Arresting Gears				
	MK7-1	MK7-2	MK7-3	M-21	E-15
10,000	Fig. 14.1	Fig. 16.1	Fig. 18.1	Fig. 20.1	Fig. 22.1
15,000	Fig. 14.2	Fig. 16.2	Fig. 18.2	Fig. 20.2	Fig. 22.2
20,000	Fig. 14.3	Fig. 16.3	Fig. 18.3	Fig. 20.3	Fig. 22.3
30,000	Fig. 14.4	Fig. 16.4	Fig. 18.4	Fig. 20.4	Fig. 22.4
40,000	Fig. 14.5	Fig. 16.5	Fig. 18.5	Fig. 20.5	Fig. 22.5
50,000	Fig. 14.6	Fig. 16.6	Fig. 18.6	Fig. 20.6	Fig. 22.6
60,000	Fig. 14.7	Fig. 16.7	Fig. 18.7	Fig. 20.7	Fig. 22.7

5.2.3 Oscillatory nondimensional load-stroke curves. Because of cable dynamics there is an oscillatory force during each arrestment. For each nondimensional load-stroke curve shown herein, the oscillatory nondimensional load is shown superimposed on the mean load-stroke curve. Actually, the oscillatory load must be also superimposed on the upper as well as the lower 90-90 probability load curves. The dotted line on each diagram represents the upper limit of the oscillatory load about the upper 90-90 envelope boundary and therefore contains the highest value of peak load during an arrestment. It should be noted that the amplitude and the frequency of the oscillatory curves are average values and that frequency can vary as much as one half cycle in either direction from that shown. Therefore, in extracting the maximum nondimensional load from the curves listed in Table 36, allowance must be made

for the frequency variation so that the peaks of the oscillatory and the smooth curves coincide. The average half amplitudes and average frequencies for each arresting gear and specific weight of Table 36 are shown in Figures 15.3, 17.3, 19.3, 21.3 and 23.3 as a function of nondimensional stroke. To obtain average half amplitudes and frequencies for intermediate airplane weights, linear interpolation must be used.

5.2.4 Runout. The values of runout vary for each arresting gear. The runout value must be used in obtaining dimensional values from the nondimensional load-stroke curves.

5.2.4.1 Runout for shipboard arrestments. The runouts for the MK7-1, MK7-2, and MK7-3 gears are 230, 310, and 340 feet respectively.

5.2.4.2 Runout for shorebased arrestments. The runout is variable and can be obtained from Figure 21.6, and Figure 23.1 as a function of airplane weight and/or engaging speed. For calculating loads, the mean value of the runout must be used for emergency arrestments. For routine shorebased arrestments, runouts associated with the mean and upper 90-90 loads are to be used.

5.2.5 Engaging speeds. Engaging speeds along with airplane weights and runout must be used for dimensioning the nondimensional load-stroke curves.

5.2.5.1 Engaging speeds for normal arrestments. Engaging speeds up to the limit engaging speeds shown in Figures 15.1, 17.1, 19.1 and 21.1 for the MK7-1, MK7-2, MK7-3, and M-21 gears may be used.

5.2.5.2 Engaging speeds for emergency arrestments. Engaging speeds up to 160 knots may be used.

5.2.6 Corrections to the nondimensional diagrams. It was pointed out in Section 4 that the nondimensional diagrams are correct for only certain base conditions. Therefore some corrections are required to make the diagrams applicable to the general case.

5.2.6.1 Corrections for routine arrestments.

5.2.6.1.1 Corrections for thrust and engaging speed. In Section 4 it was stated that the area of the nondimensional diagrams is nearly constant for the base thrust and engaging speed for each arresting gear. The base thrust is a constant $0.4W$ during the runout for the shipboard gears and is as shown in Figure 24 for the M-21 gear. The base engaging speeds are 130 knots, 135 knots, 145 knots and 160 knots for the MK7-1, MK7-2, MK7-3, and M-21 gears, respectively. To make the diagrams applicable to the general case the area and the nondimensional load (including the oscillatory load) have to be multiplied by a correction factor. This factor is the ratio of the area of the nondimensional diagram for any engaging speed and thrust to the area of the nondimensional diagram corresponding to the base thrust and engaging speed. The correction factor is given by the following equation:

$$C = \frac{\left[.5 MV^2 + TR - k_1 WR - k_2 \int_0^R V_i^2 dx \right] V_B^2}{\left[.5 MV_B^2 + T_B R - k_1 WR - k_2 \int_0^R V_{i_B}^2 dx \right] V^2}$$

where: $k_1 = .017$, coefficient of rolling friction,

$k_2 = (.011 + 2.2 \times 10^{-6} W)$ aerodynamic drag
coefficient, $\text{lbs} \frac{\text{sec}^2}{\text{ft}^2}$

$V_i =$ instantaneous velocity, ft/sec,

and the subscript B for V and T refers to the base cases for which the nondimensional diagrams are presented.

Plots of correction factors for selected values of thrust are shown in Figures 15.2, 17.2, 19.2, and 21.2 as a function of engaging speeds. If, for a particular airplane, the values of the coefficients and thrust are different than those appearing here, the applicable parameters can be substituted into the numerator above to obtain a more accurate correction factor.

5.2.6.1.2 Correction for wet tape. When the M-21 arresting gear tape is wet oscillatory loads increase. Figure 21.7 gives the correction factor for this situation.

5.2.6.2 Correction for emergency engagements. The correction factor for the E-15 gear is 1.0 since it is assumed that the thrust is always equal to drag during the arrestment. Figure 23.2 gives the correction factor for converting 300 foot span to 200 foot span.

5.2.7 Diagram dimensional load scale. For each nondimensional diagram a base dimensional load scale is given. To obtain a dimensional value for other than base conditions corrections as shown at the bottom of each diagram must be made.

5.2.8 Peak arresting force. The peak arresting force can be obtained from the nondimensional load stroke diagrams. For easy reference the maximum and mean peak arresting forces have been plotted as a function of engaging speed for different values of weights. These are shown in Figures 15.4, 15.5, 17.4, 17.5, 19.4, 19.5, 21.4, 21.5, 21.8, 23.4 and 23.5. Peak values for intermediate weights can be approximated by visual interpolation.

5.2.9 Sample of calculations.

MIL-STD-2066(AS)

5.2.9.1 Sample of calculations for normal arrestments.

Given data: Airplane weight - 17,500 pounds
 Airplane thrust - 7,500 pounds (.43W)
 MK7-1 arresting gear
 Engaging speed - 100 knots

Data to be determined: (a) Peak arresting force for the upper 90-90 probability with and without the oscillatory force; also, corresponding forces at the same stroke for the mean and lower 90-90 probability.
 (b) Load-stroke curves for the upper 90-90 probability including the oscillatory force.

Solution: (a) By inspecting Figure 14.2 for 15,000 pounds weight, and Figure 14.3 for 20,000 pounds it appears that the peak force 17,500 pounds will occur at $X/R = .23$. (In cases where this is not immediately apparent a trial and error method may be used.) Calculation of the nondimensional load is shown in Table 37, where the values of the first two rows of nondimensional load without the oscillatory for weight of 15,000 pounds and 20,000 pounds are obtained from Figures 14.2 and 14.3. The nondimensional component of the oscillatory load for 15,000 and 20,000 at $X/R = .23$ is obtained from Figure 15.3. The values of the second through the fifth column of the third row for 17,500 pounds weight are found by interpolation. The values of the last three columns of the third row are the values of the nondimensional load including the oscillatory component.

Substituting in the formula of 4.1 the values of L from Table 37, 17,500/32.2 slugs for M, 100 x 1.69 ft/sec for V, 230 ft for R, 1.09 for C (see Figure 15.2) and solving for F, the following peak arresting forces are obtained.

$$F_M = .625 \times 1.09 \left(\frac{17,500}{32.2} \right) \frac{(100 \times 1.69)^2}{230} = 45,900 \text{ lbs}$$

$$F_{M+osc} = .833 \times 1.09 \left(\frac{17,500}{32.2} \right) \frac{(100 \times 1.69)^2}{230} = 61,200 \text{ lbs}$$

$$F_U = .762 \times 1.09 \left(\frac{17,500}{32.2} \right) \frac{(100 \times 1.69)^2}{230} = 56,000 \text{ lbs}$$

$$F_{U+osc} = .970 \times 1.09 \left(\frac{17,500}{32.2} \right) \frac{(100 \times 1.69)^2}{230} = 71,300 \text{ lbs}$$

$$= .488 \times 1.09 \left(\frac{17,500}{32.2} \right) \frac{(100 \times 1.69)^2}{230} = 35,900 \text{ lbs}$$

$$= .696 \times 1.09 \left(\frac{17,500}{32.2} \right) \frac{(100 \times 1.69)^2}{230} = 51,100 \text{ lbs}$$

(b) To obtain the load-stroke curve for the upper 90-90 probability including the oscillatory force the following step-by-step procedure is used:

- (1) obtain the upper 90-90 probability nondimensional load-stroke curve for a gross weight of 17,500 pounds without the oscillatory. This can be readily done by reading at various values of stroke the corresponding values of the nondimensional load without the oscillatory for weights of 15,000 and 20,000 pounds from Figure 14.2 and 14.3, and then interpolating to obtain the upper 90-90 probability nondimensional load for 17,500 pounds. The results of this interpolation are shown in column 5 of Table 38.
- (2) Superimpose on the values of column 5, Table 38, the envelope of the peaks and bottom of the troughs of the oscillatory nondimensional load. This can be done by reading the values of the half amplitudes of the oscillatory nondimensional load for weights of 15,000 and 20,000 pounds from Figure 15.3 at various values of the nondimensional stroke and then interpolating for 17,500 pounds. Results of this interpolation are shown in column 8 of Table 38. Then by adding to and alternately subtracting column 8 from column 5, superimposition is completed and the results are shown in columns 9 and 10 of Table 38.

MIL-STD-2066(AS)

- (3) Dimensionalize the nondimensional loads of (1) and (2). This is simply done by multiplying columns 5, 9, and 10 by 1.09 $(17,500/32.2) \times (100 \times 1.69)^2/230 = 73,475$ pounds, as explained in part (a) of this example. The dimensional loads are shown in columns 11, 12, and 13 of Table 38 and are also plotted in Figure 25.
- (4) Locate points of tangency and intersection of the upper 90-90 load (including oscillatory loads) with each of the three curves of Figure 25. Since as it was pointed out in 5.2.3 the frequency of the oscillatory component of the load is a variable, an infinite number of points can be located. For this example the frequency of the oscillatory component of the load will be adjusted so that the upper 90-90 probability load plus its oscillatory component will be maximum. From inspection of Figure 25 this maximum occurs at a stroke of 52.9 feet. To determine the points of tangency and intersection, Table 39 is constructed. Derivation of the first six columns is self explanatory. The seventh column is obtained by adjusting the number of cycles of column 6 so that the upper 90-90 probability load plus its oscillatory component will be maximum with the least amount of frequency adjustment. From column 6 it is noted that at a stroke of 52.9 feet the number of average cumulative cycles is 2.939. This number has to be adjusted to 3.25 cycles so that the peak of the oscillatory component will occur at a stroke of 52.9 feet. Therefore, the cycles of column 6 are multiplied by the ratio of 3.25/2.939, as shown in column 7. Column 8 shows the adjusted number of cycles per interval and it is obtained as the difference of two successive cumulative cycles of column 7. To obtain the points of tangency and intersection of the oscillatory with each of the three curves of Figure 25, the following observations are made:
1. Intersection with the middle curve will occur when the number of cycles is equal to zero and each half cycle thereafter.
 2. Tangency with the upper or the lower curve will occur when the number of cycles is equal to .25 and each half cycle thereafter.

To obtain any intersection or tangency point, say for instance a point for 6 cycles (intersection), it is noted from Table 39 (column 7) that this point will correspond to a stroke greater than 92 feet and that another .752 of a cycle $(6 - 5 \times 248)$ is required to complete the 6th cycle. Therefore, the corresponding value of the stroke will be:

$$92 + \frac{.752 \times \text{interval}}{\text{adjusted cycles per interval}} = 92 + \frac{.752 \times 23}{1.073} = 108.1 \text{ feet}$$

MIL-STD-2066(AS)

MIL-STD-2066(AS)

By the same method the remainder of the intersection points and all the tangency points are found and are shown as small circles on Figure 25. An alternate graphical method of plotting Table 39 column 1 versus column 7 and then reading the quarter cycle intersections directly will expedite the solution. By drawing on Figure 25 a smooth curve tangent to the upper and lower curve at the small circles and intersecting the middle line at the small circles, the load-stroke curve for the upper 90-90 probability, including its oscillatory component, is determined.

5.2.9.2 Sample of calculations for emergency arrestments.

Given data: Airplane weight - 45,000 pounds
E-15 arresting gear (300 foot span)
Engaging speed 155 knots

Data to be determined: Peak arresting force for the upper 90-90 probability with and without its oscillatory component

Solution: By inspecting Figures 22.5 and 22.6, it appears that at $X/R = .53$ the peak arresting force will develop. The values of L_u of Table 40 are obtained from Figures 22.2 and 22.6. The value of L_{osc} is obtained from Figure 23.3 and the third row for 45,000 pounds is obtained by interpolation.

Additionally, from Figure 23.1, the value of the runout R , of 1,020 feet for 155 knots is obtained. Substituting in the formula of 4.1 the values of L from Table 40, 45,000/32.2 slugs for M , 155 x 1.69 ft./sec for V , 1,020 feet for R and solving for F the following is obtained:

$$F_u = .798 \times \left(\frac{45,000}{32.2} \right) \times \frac{(155 \times 1.69)^2}{1,020} = 74,900 \text{ lbs}$$

$$F_{u+osc} = .844 \times \left(\frac{45,000}{32.2} \right) \times \frac{(155 \times 1.69)^2}{1,020} = 79,250 \text{ lbs}$$

The above calculated load (including oscillation) can be read directly using Figures 23.4 and 23.5 The load-stroke curve may be obtained using the same procedure as in the previous example.

EFFECTS OF AERODYNAMIC DRAG AND ROLLING FRICTION INCLUDED

Aerodynamic Drag, $D_d = (.011 + 2.2 \times 10^{-6} W) V_d^2$

Rolling Friction = .017W

where D_d = aerodynamic drag at any instant, pounds V_d = velocity at any instant, feet/second

W = airplane weight, pounds

*Dimensioned scale for upper 90-90 loads, 160 knots engaging speed, thrust of .4W, and drytapes only. Other engaging speeds and thrust values require correction per ratio $\frac{V_E^2/R}{160.2/680.37.65R}$ or $V_E^2 \times$ correction factor \times dimensioned scale. V_E is in knots and runout R is from Figure 21.6 and is in feet.

FIGURE 20.1. M-21 Gear, 10,000 Lb Weight, Load vs Stroke, Nondimensional

*Dimensioned scale for upper 90-90 loads, 160 knots engaging speed, thrust of .4W, and drytapes only. Other engaging speeds and thrust values require correction per ratio $\frac{V_E^2/R}{160.2^2/680.37.65R}$ or $V_E^2 \times$ correction factor x dimensioned scale. V_E is in knots and runout R is from Figure 21.6 and is in feet.

STANDARDIZATION DOCUMENT IMPROVEMENT PROPOSAL	
<p>INSTRUCTIONS: This form is provided to solicit beneficial comments which may improve this document and enhance its use. DoD contractors, government activities, manufacturers, vendors, or other prospective users of the document are invited to submit comments to the government. Fold on lines on reverse side, staple in corner, and send to preparing activity. Attach any pertinent data which may be of use in improving this document. If there are additional papers, attach to form and place both in an envelope addressed to preparing activity. A response will be provided to the submitter, when name and address is provided, within 30 days indicating that the 1426 was received and when any appropriate action on it will be completed.</p> <p>NOTE: This form shall not be used to submit requests for waivers, deviations or clarification of specification requirements on current contracts. Comments submitted on this form do not constitute or imply authorization to waive any portion of the referenced document(s) or to amend contractual requirements.</p>
